Purpose of the Dive

This extinct arc volcano is the last unexplored large arc seamount in the southern Marianas. Its summit region was expected to host extinct hydrothermal fields and mature summit communities, including fisheries. This dive was planned to begin at 1349 m, and to traverse 486 m upslope to the south, with the goal to reach the seamount summit (1198 m) and then explore along the summit.

Description of the Dive:

The dive began at a depth of 1319 m on the upper slope of the NW Guam Seamount. We slowly traversed upslope to the south through sedimented, weathered outcrops and talus all coated with a manganese crust. The Mn crust was quite heavy, with a pebbled or botryoidal texture. There were some areas with a platey or sheet-like texture, but it was impossible to tell its lithology. About two hours into the dive, we encountered a dike outcrop, with columnar jointing and fractures (rock collected here – D2_DIVE08_SPEC02GEO). After reaching the summit, we flew down to the saddle between two of the local highs and headed upslope to the west. In this area, the sediment showed ripple marks and was later stratified into dark and light sediments with sinuous, low-relief mounds. The few outcrops encountered on the second slope were heavily weathered and covered in Mn crust.

The biology on this dive was very exciting, with many new sightings for this expedition! It included many octocorals with commensal ophiuroids and chirostylid squat lobsters, as well as many antipatharians, likely *Trissopathes*. There were also many interesting fish noted: a hagfish, a *Hydrolagus* chimaera, and a sedentary angler. There was also a large lobster encountered guarding a very extensive burrow network, perhaps *Acanthacaris* sp. There were also several echinoderms including several Echinothuriidae urchins and a likely new genus of stalked crinoid.
